

Toy 2: sparse snapshot memory

Marker states appear every $K = 4$ steps; the lower strip denotes a nuisance channel that is not predictive by itself.

$$y \sim 1.15 s_{last} - 0.85 s_{prev} + 0.55 s_{old} + 0.06 \tanh(n_{t-1})$$

Recovering the last three marker states requires sparse historical extraction rather than local smoothing.
